## WOLVERTRIMIPTON ASTRONOMICNL SOGIETY

## HRE SUMENB NHGET SET

The above star chart shows the aspect of the sky from Wolverhampton on 2017 July 16 at 23:00ut.

The Summer Night Sky covers the period from June 2017 through to early September 2017. All times given below (mainly for sunrise, sunset, occultations, and eclipses) are Universal Time (UT) unless otherwise stated, so please remember to add one hour for when British Summer Time (BST) is in force. The times of sunrise, sunset, eclipses and those of occultations are correct for Wolverhampton.

## THIS SUN

The principle times of sunrise and sunset during the summer are given in the table below, together with the solar diameter, altitude that the Sun transits the meridian on that day, seen from Wolverhampton, and the constellation in which the Sun appears on that day:

| DATE | SUNRISE | TRANSIT | TRANSIT ALTITUDE | SUNSET | SUN'S DIAMETER | CONSTELLATION |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| JUN 1 | 03:51 UT | 12:06 UT | 59.5 ${ }^{\circ}$ | 20:22 UT | 31.5 ' | Taurus |
| JUN 6 | 03:48 UT | 12:07 UT | $60.1{ }^{\circ}$ | 20:27 UT | $31.5{ }^{\prime}$ | Taurus |
| JUN 11 | 03:45 UT | 12:08 UT | $60.5^{\circ}$ | 20:31 UT | 31.5 | Taurus |
| JUN 16 | 03:45 UT | 12:09 UT | $60.8{ }^{\text {o }}$ | 20:34 UT | $31.5{ }^{\prime}$ | Taurus |
| JUN 21 | 03:45 UT | 12:10 UT | $60.8{ }^{\text {o }}$ | 20:36 UT | 31.5 | Taurus |
| JUN 26 | 03:47 UT | 12:11 UT | $60.8{ }^{\text {o }}$ | 20:36 UT | $31.5{ }^{\prime}$ | Gemini |
| JUL 1 | 03:50 UT | 12:12 UT | $60.5^{\text {o }}$ | 20:35 UT | 31.5 | Gemini |
| JUL 6 | 03:54 UT | 12:13 UT | $60.0^{\circ}$ | 20:32 UT | 31.5 | Gemini |
| JUL 11 | 03:59 UT | 12:14 UT | $59.4{ }^{\text {º}}$ | 20:29 UT | 31.5 | Gemini |
| JUL 16 | 04:05 UT | 12:15 UT | $58.7^{\text {º}}$ | 20:23 UT | 31.5 ' | Gemini |
| JUL 21 | 04:12 UT | 12:15 UT | $57.8^{\circ}$ | 20:17 UT | 31.5 | Cancer |
| JUL 26 | 04:19 UT | 12:15 UT | $56.7^{\circ}$ | 20:10 UT | 31.5 | Cancer |
| JUL 31 | 04:27 UT | 12:15 UT | $55.6{ }^{\circ}$ | 20:02 UT | 31.5 | Cancer |
| AUG 5 | 04:35 UT | 12:14 UT | $54.2^{\circ}$ | 19:53 UT | 31.5 ' | Cancer |
| AUG 10 | 04:43 UT | 12:14 UT | $52.8{ }^{\text {o }}$ | 19:44 UT | 31.6' | Cancer |
| AUG 15 | 04:51 UT | 12:13 UT | $51.3^{\circ}$ | 19:34 UT | 31.6 ' | Leo |
| AUG 20 | 04:59 UT | 12:12 UT | $49.7^{\circ}$ | 19:23 UT | $31.6^{\prime}$ | Leo |
| AUG 25 | 05:08 UT | 12:11 UT | $48.0^{\circ}$ | 19:12 UT | 31.6 ' | Leo |
| AUG 30 | 05:16 UT | 12:09 UT | $46.2^{\text {º }}$ | 19:01 UT | 31.7 | Leo |
| SEP 4 | 05:24 UT | 12:07 UT | $44.4{ }^{\text {º }}$ | 18:49 UT | 31.7 ' | Leo |
| SEP 9 | 05:33 UT | 12:06 UT | $42.5^{\circ}$ | 18:38 UT | 31.8' | Leo |

## RHE MOON

The principle phases of the Moon during the summer are given in the table below, together with the lunar diameter, altitude that the Moon transits the meridian on that day, seen from Wolverhampton, and the constellation in which the Moon appears on that day:

|  | PHENOMENON | DATE | TIME | TRANSIT <br> ALTITUDE | MOON'S <br> DIAMETER | CONSTELLATION |  |
| :--- | :--- | :--- | :---: | :--- | :---: | :---: | :--- |
| First Quarter | JUN | 1 | $12: 42$ UT | $45.1^{\circ}$ | $31.1^{\prime}$ | Leo |  |
|  | Full Moon | JUN | 9 | $13: 10$ UT | $18.6^{\circ}$ | $29.0^{\prime}$ | Ophiuchus |
|  | Last Quarter | JUN | 17 | $11: 33$ UT | $32.9^{\circ}$ | $31.3^{\prime}$ | Aquarius |
|  | New Moon | JUN | 24 | $02: 31$ UT | $55.8^{\circ}$ | $33.2^{\prime}$ | Orion |

|  | PHENOMENON | DATE |  | TIME | TRANSIT ALTITUDE | MOON'S DIAMETER | CONSTELLATION |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| (D) | First Quarter | JUL | 1 | 00:51 UT | $36.2^{\circ}$ | 30.4' | Virgo |
| $\bigcirc$ | Full Moon | JUL | 9 | 04:07 UT | $17.4{ }^{\circ}$ | 29.7' | Sagittarius |

| $\bigcirc$ | Last Quarter | SEP | 13 | 06:25 UT | 55.3 ㅇ | 32.8' | Taurus |

## RHIE Phanturs

The illustrations above show the planets as they appear this summer. The images are to scale, with Mercury, Venus, and Mars on the 1st June, and $16^{\text {th }}$ July respectively. Jupiter and Saturn have only single illustrations, taken on 16 th July.

Mercury - is a morning object at first, but quickly closes with the Sun in the sky to be at superior conjunction on 21 ${ }^{\text {st }}$ June.

Mercury then becomes an evening object, not too badly placed in the British Isles. The planet is at greatest eastern elongation $\left(27^{\circ}\right)$ on $30^{\text {th }}$ July, when Mercury will be setting just over $3 / 4$ hour after the Sun. Mercury is however brightest before this date. As the summer progresses, Mercury continues to wane, and takes on a large but faint crescent phase. It will then be an extremely difficult object to observe.

Mercury disappears from view in early August, to be at inferior conjunction on $26^{\text {th }}$ August. Mercury then emerges in the morning sky to become a well-placed object, and is at greatest western elongation $\left(18^{\circ}\right)$ on $12^{\text {th }}$ September. The planet will however, be brighter after this date, as Mercury waxes into a small gibbous phase.

A thin waxing crescent Moon passes Mercury on the evening of $25^{\text {th }}$ July. Both objects will be low in the north-west. A very thin waning crescent Moon, only two days from New Moon passes north of both Mercury and Mars on $18^{\text {th }}$ September.

Venus - is a morning object, and is at greatest western elongation $\left(46^{\circ}\right)$ on $3^{\text {rd }}$ June. On this date, Venus displays a phase similar to the Last Quarter Moon through a telescope. Only Venus is waxing, but shrinking in size as it continues to recede from us. In early June, Venus rises $11 / 2$ hours before the Sun. This interval increases to about 3 hours before the Sun by the end of August.

The waning crescent Moon passes south of Venus on the early mornings of $20^{\text {th }}$ and $21^{\text {st }}$ June. Again, the waning crescent Moon passes south of Venus on the early morning of $20^{\text {th }}$ July. Yet again, the waning crescent Moon passes south of Venus on the early morning of $19^{\text {th }}$ August.

Earth - The Earth is at Aphelion on 3rd July at 20:11UT, with a distance of just over 152 million kilometers ( 95 million miles) from the Sun. Consequently, the Sun reaches a minimum angular diameter of 31.5 arcminutes in our sky.

The Summer Solstice occurs on $21^{\text {st }}$ June at 04:24UT. On this day, from Wolverhampton the Sun transits the meridian with a maximum altitude of 60.8 degrees above the southern horizon.

However, from Wolverhampton the earliest sunrise occurs on 17 ${ }^{\text {th }}$ June at 03:45UT, and the latest sunset occurs on $24^{\text {th }}$ June at 20:36UT, due to the effects of the Equation of Time.

Mars - is a faint evening object in the bright evening twilight sky. The planet is moving rapidly direct through Taurus, setting little over 1 hour after the Sun at the beginning of June, but is soon lost in the bright twilight sky. Mars is at conjunction on $27^{\text {th }}$ July, and becomes a morning object thereafter. By the very end of August, Mars is a morning object in Leo, rising about 1 hour before the Sun.

Jupiter - is an evening object in Virgo. Jupiter, now past opposition, reaches its second stationary point on $10^{\text {th }}$ June, after which it resumes its normal direct motion among the stars of Virgo. At the beginning of June, Jupiter sets at by 01:15UT. As the summer progresses, Jupiter will set earlier and earlier, and by late August Jupiter will be setting by 20:14UT, which is barely $11 / 4$ hours after sunset.

The waxing gibbous Moon passes to the north of Jupiter on the evening of $3^{\text {rd }}$ June, and again, the First Quarter Moon passes to the north of Jupiter on the evenings of $30^{\text {th }}$ June and $1^{\text {st }}$ July. Finally, yYet again, the wide waxing crescent Moon passes to the north of Jupiter on the evening of $28^{\text {th }}$ July, and finally, the narrow waxing crescent Moon passes to the north of Jupiter on the evening of $25^{\text {th }}$ August.

Saturn - is at opposition on $15^{\text {th }}$ June, with the ringed planet slowly retrograding in Ophiuchus, and the planet reaching an altitude of 15.4 degrees at culmination in the south, seen from Wolverhampton. Saturn is quite far south now, and only makes low passes in our skies. However, the ringed planet makes up for this by having its ring system fully open to us, displaying the northern aspect of the rings. By the end of August, Saturn sets at 22:46UT, but will still be well on view.

The nearly Full Moon passes north of Saturn on the night of $9^{\text {th }}$ June. Again, the waxing gibbous Moon passes north of Saturn on the night of $6^{\text {th }}$ July, and yet again, the waxing gibbous Moon passes north of Saturn on the night of $2^{\text {nd }}$ August. Finally, the just past First Quarter Moon passes north of Saturn yet again on the evening of $30^{\text {th }}$ August.

Uranus - is a faint morning object in the eastern part of Pisces. Uranus reaches its first stationary point on $3^{\text {rd }}$ August, and then begins its retrograde motion. The ice giant rises at 02:14UT at the beginning of June, and by $20: 14 \mathrm{UT}$ by the end of August.

The planet Venus passes $13 / 4$ degrees to the south of Uranus on the early morning of $3^{\text {rd }}$ June, which should help identification with binoculars.

The waning crescent Moon passes south of Uranus on the mornings of $19^{\text {th }}$ and $20^{\text {th }}$ June. Again, the almost Last Quarter Moon passes south of Uranus on the morning of $17^{\text {th }}$ July. Finally, the waning gibbous Moon passes south of Uranus on the morning of $13^{\text {th }}$ August.

Neptune - is a very faint morning object in the eastern part of Aquarius. Neptune reaches its first stationary point on $16^{\text {th }}$ June, and then also begins its retrograde motion. This far ice giant rises at 01:06UT at the beginning of June, and is above the horizon all night by the end of August, being at opposition on $5^{\text {th }}$ September, with the planet reaching an altitude of 29.8 degrees at culmination in the south, seen from Wolverhampton.

The waning gibbous Moon passes to the south of Neptune on the early mornings of $16^{\text {th }}$ and $17^{\text {th }}$ June. Again, the waning gibbous Moon passes to the south of Neptune on the early morning of $14^{\text {th }}$ July. Yet again, the waning gibbous Moon passes to the south of Neptune on the early morning of $10^{\text {th }}$ August. Finally, the Full Moon passes to the south of Neptune on $6^{\text {th }}$ September.

## EGHPSEAS

During the summer, there will be two eclipses. A Partial Lunar Eclipse on $7^{\text {th }}$ August, and a Total Solar Eclipse on $21^{\text {st }}$ August.

Total Solar Eclipse 21st August 2017

## 1. Partial Lunar Eclipse - $7^{\text {th }}$ August

A partial lunar eclipse occurs on the $7^{\text {th }}$ August. This eclipse, belonging to Saros 119 , is visible from central and eastern parts of Africa, Asia, India, the Indian Ocean, Malaysia, Indonesia and Australia. The point of greatest eclipse occurs at 18:22UT, when the greatest umbral magnitude of 0.2464 will be reached. Unfortunately, the eclipse is not visible in the British Isles, as the event occurs below our horizon, and from Wolverhampton the Moon does not rise until 19:41UT.

This eclipse, belonging to Saros 119 occurs near the Moon's descending node, and is moving northwards through the Earth's shadow. The series is an old one, and is now past its total phase; the last total eclipse occurring in June 1927. The series will continue to produce partial umbral eclipses of diminishing magnitude until August 2053, when a total penumbral eclipse occurs. After this eclipse the series produces its terminal partial penumbral eclipses, until the series ends in March 2360.

## 2. A Total Solar Eclipse - 21 ${ }^{\text {st }}$ August

A Total solar eclipse occurs on $21^{\text {st }}$ August. This eclipse, belonging to Saros 145, whose track of totality is visible from the United States states of Oregon, Idaho, Wyoming, Nebraska, Kansas, Missouri, Kentucky, Tennessee, Georgia and South Carolina.

A partial eclipse is generally visible from Alaska, Canada, the parts of the USA adjacent to the track of totality, and the wider USA, Mexico, the Caribbean, and the northern parts of South America.

The point of maximum eclipse lies to the north-west of Hopkinsville, Kentucky, where a magnitude of 1.0306 is attained, together with a duration of totality of 2 m 40 s , and the Sun at an altitude of 63.9 degrees.

A map showing the visibility of the eclipse and local circumstances follow below.

Total Solar Eclipse over North America • August 21, 2017

Local Circumstances of the Eclipse

Above: Maximum eclipse from various locations in North America. These images have been reproduced with kind permission from the Redshift software.

This eclipse, belonging to Saros 145 occurs near the Moon's ascending node, and is moving southwards on the Earth's surface. The series began in 1639 with the first small partial eclipse in the Arctic. The series quickly produced partial eclipses of ascending magnitude, and produced an Annular eclipse in northern Siberia in June 1891. As the Moon continued to approach the Earth at each successive eclipse, the series quickly became total, producing a hybrid eclipse in the Arctic in June 1909. The next eclipse at the end of June 1927 was fully total, and crossed the British Isles from North Wales, through Lancashire, Yorkshire, and out into the North Sea at Teesside.

The series continued to produce total eclipses of lengthening duration, including the well-remembered eclipse of August 1999 which crossed Cornwall and southern Devon.

After 2017, the series crosses China, North Korea and Japan in September 2035. After re-visiting the British colony of Gibraltar in September 2053, the duration of totality falls off slightly, before increasing markedly afterwards. The series reaches its maximum duration in June 2522 with totality reaching 7 m 12 s . After this, the series rapidly declines, producing its last total eclipse in September 2648. After a series of partial eclipses of declining magnitude in the Antarctic, the series finally ends in April 3009.

## OGCULPAYIONS

During the summer, there are no occultations of any planets or stars brighter than third magnitude suitably visible.

## Mizmisors

The Perseids - During the summer, the main meteor shower are the Perseids. These are visible between $23^{\text {rd }}$ July and $20^{\text {th }}$ August. They reach their peak on the morning of $13^{\text {th }}$ August.

## EXTRA-TERRESTRIAL EVENTS

From Mercury - Mercury is at perihelion on $19^{\text {th }}$ June. The Sun's apparent diameter in the Mercurian sky will then be at its maximum; 104.2 arcminutes, which is about $31 / 4$ times the diameter that we see the Sun in our own Earth sky. At this time, the overhead, perihelic Sun will be thundering down, baking the Caloris Basin, the hottest part of Mercury.

Mercury is at aphelion on $2^{\text {nd }}$ August, and by this time, the apparent solar diameter will have shrunk to a mere 68.5 arcminutes, which is just over twice the diameter that we see the Sun in our own Earth sky. From the Caloris Basin, the much-reduced Sun is setting in the west, being overhead 90 degrees further west of this location.

Venus is in conjunction on $5^{\text {th }}$ July, and moves to the west of the Sun thereafter as a morning object on the border of Cetus and Pisces. Magnitude -4.7, diam 14.7".

The Earth is also in conjunction on $21^{\text {st }}$ June, and becomes a morning object. The Blue Planet is then at opposition on $26^{\text {th }}$ August in Aquarius, magnitude-4.8, diam 28.2". The Moon shines alongside the Earth, displaying the same phase, and reaches a magnitude of -0.7 , diam 7.7". At this time, the Moon can elongate up to 14 arcminutes either side of the Earth.

Mars is at opposition on $24^{\text {th }}$ June in Gemini, magnitude +0.1 , diam 7.2".
Of the Giant planets, Jupiter is at opposition on $15^{\text {th }}$ July in Virgo, magnitude -2.1, diam 39.2". Saturn is at opposition on $5^{\text {th }}$ August in Ophiuchus, magnitude +0.2 , diam 17.2".

From Venus - Venus is at aphelion on $13^{\text {th }}$ June. The Sun's apparent diameter in the Venusian sky will then be at its minimum; 43.9 arcminutes, which is about $11 / 2$ times the diameter that we see the Sun in our own Earth sky. The diameter of the Sun in the Venusian sky does not vary that much, as the Venusian orbit is much less eccentric than that of the Earth.

Mercury is at superior conjunction on $5^{\text {th }}$ July, and then moves east of the Sun, magnitude -1.4, diam 5.9". Phase 98\%.

The Earth lies to the east of the Sun in the Venusian sky, in the constellation of Virgo, and is a brilliant object at quadrature on $3^{\text {rd }}$ June. This renders the blue planet at its minimum phase of $84 \%$, magnitude -3.9 , diam 25.1". The Moon shines alongside the Earth, displaying the same phase, and reaches a magnitude of +0.8 , diam 6.8". At this time, the Moon can elongate up to 13 arcminutes either side of the Earth.

Mars lies west of the Sun in the Venusian sky, moving rapidly through Cancer, Leo and Virgo. Magnitude +1.4 , diam 4.6"

Jupiter is in conjunction on $30^{\text {th }}$ July, but quickly emerges to the west of the Sun thereafter, lying in Virgo magnitude-1.6, diam 31.9".

Saturn lies to the west of the Sun, in Ophiuchus, magnitude +0.5 , diam 16.2".

From Mars - Mars was at perihelion last October, and is now moving away from the Sun in its orbit. The Sun's apparent diameter in the Martian sky is getting smaller, and by mid-July this is only 19.6 arcminutes, just under twothirds the diameter we see the Sun in our own Earth sky. This is noticeably smaller than it was in April, due to Mars' greater orbital eccentricity than that of the Earth.

Mercury is at inferior conjunction on $24^{\text {th }}$ June, and is a morning object thereafter. Elongations of Mercury are small seen from Mars, and Mercury can never elongate more than about 14 degrees east or west of the Sun in the sky. Also, another consideration is the Martian dust which hangs in the sky obscuring the sky toward the horizon, and lengthening twilights. All these things would hamper any observations of a difficult planet like Mercury. Magnitude

Venus is an evening object in the Martian sky, moving rapidly direct through Sagittarius, Capricornus and Aquarius. This favours the Martian northern hemisphere for observation at this time. Venus is at greatest eastern elongation ( $26^{\circ}$ ) on $28^{\text {th }}$ August, and Venus sets about 3 hours after the Sun from the equivalent latitude of Wolverhampton. Venus is at inferior conjunction in September. Magnitude -1.7, diam 11.1", phase $50 \%$.

The Earth is a morning object in the Martian sky, but is lost in the bright dusty morning twilight. The Blue Planet is at superior conjunction on $27^{\text {th }}$ July, and becomes an evening object thereafter. Through a telescope, the Earth exhibits a tiny, but full disk. Little detail would be discernable with the planet on the opposite side of its orbit, beyond the Sun as seen from Mars. Magnitude -1.7, diam 6.6", phase 100\%.

Earth's Moon shines alongside its parent planet at magnitude +2.4 , diam 1.8 ", phase $100 \%$. At this time, the Moon can elongate about $31 / 2$ arcminutes either side of the Earth.

Of the outer planets, Jupiter is a morning object in Libra, shining at magnitude -1.8 , diam. 35.2". Saturn, having been in conjunction on $1^{\text {st }}$ May, is now a morning object in Sagittarius, magnitude +0.8 , diam 14.5"

Uranus is an evening object in Pisces, mag. +5.8 , diam. 3.5", and finally, Neptune is an evening object in Aquarius, mag. +8.0, diam. 2.2".

From Jupiter - Jupiter was at aphelion last February. Jupiter is now moving very slowly sunward. As a result, the Sun's apparent diameter in the Jovian sky is 352.1 arcseconds ( 5.9 arcminutes). This is just under a fifth the diameter that we see the Sun in our own Earth sky.

The inner planets are not normally covered here, as they would be too close to the Sun in the Jovian sky. Venus would elongate only 8 degrees from the Sun. The Earth would fare little better, elongating between 10 and 11 degrees, and shining at around mag. +1.5 , diam. $3.3^{\prime \prime}$. Mars would elongate about 14 degrees from the Sun, but would be much fainter and smaller than Venus or Earth.

The brightest planet in the Jovian sky would be Saturn, which would be about as bright as Jupiter in our skies when at opposition. However, this summer, the ringed planet is nowhere near opposition, and to any Jovian observer Saturn is a morning object in Sagittarius, mag. +1.4, diam. 19.0".

Uranus is in conjunction on $11^{\text {th }}$ July, and so is out of view for Jovian observers this summer. An evening object in Pisces, mag. +6.3 , diam. 2.8". Finally, Neptune is a morning object in Aquarius, mag. +8.2, diam. 2.0".

From Saturn - Saturn is approaching aphelion next year. The Sun's apparent diameter in the Saturnian sky in midJuly is 190.8 arcseconds ( 3.2 arcminutes). This is just under a tenth the diameter that we see the Sun in our own Earth sky.

This far out, the inner planets would be totally lost in the Sun's glare. The only inferior planet on view would be Jupiter. Even this can only elongate about 10 degrees either side of the Sun when at greatest elongation as seen in Saturnian skies. However, during our summer, the giant planet is an evening object on the border of Gemini and Cancer, shining at magnitude -0.4 , diam. 22.7", phase $52 \%$.

Of the outer planets, Uranus is a morning object in Aries, mag. +6.5, diam. 2.6". Finally, Neptune is a morning object in Pisces, mag. +7.9 , diam. 2.3".

From Uranus - From this ice giant, the Sun's apparent diameter in the Uranian sky in mid-July is 96.4 arcseconds ( 1.6 arcminutes). This is just about a twentieth the diameter that we see the Sun in our own Earth sky.

Also from Uranus, there are two inferior planets of note; Jupiter and Saturn. Jupiter is at superior conjunction on $11^{\text {th }}$ July, and is out of view to Uranian observers. Magnitude +1.5 , diam. 7.8 ", phase $100 \%$ Saturn is an evening object in Libra, shining much fainter than we see it, at magnitude +4.2 , diam. 6.3", phase $87 \%$, finally, the only superior planet, Neptune, is an evening object in Capricornus, magnitude +7.1 , diam. 3.3". Finally, although a Kuiper Belt object, Pluto is an evening object in Ophiuchus, magnitude +15.9, diam. 0.1".

From Neptune - From this far ice giant, the Sun's apparent diameter in the Neptunian sky in mid-July is 64.1 arcseconds ( 1.1 arcminutes). This is just about a thirtieth the diameter that we see the Sun in our own Earth sky.

All visible planets from Neptune are inferior. Jupiter is an evening object in Leo, magnitude +2.3 , diam. 5.8", phase $89 \%$. Saturn is an evening object in Virgo, magnitude +6.3 , diam. $5.6^{\prime \prime}$, phase $55 \%$. Uranus is a morning object in Cancer, magnitude +6.1, diam. 3.4", phase $45 \%$.

Finally, although a Kuiper Belt object, Pluto is an evening object in Libra, magnitude +16.3, diam. 0.1".

From Pluto - From this ice dwarf, the Sun's apparent diameter in the Plutonian sky in mid-July is 57.5 arcseconds (1.0 arcminute). This is slightly larger than we see Jupiter from Earth!

All visible planets from Pluto are inferior. Jupiter is an evening object on the border of Gemini and Cancer, very close to Saturn, magnitude +2.5 , diam. 6.0", phase $51 \%$. Saturn is also an evening object on the border of Gemini and Cancer, very close to Jupiter, magnitude +8.7 , diam. $6.8^{\prime \prime}$, phase $7 \%$. Uranus is a morning object in Taurus, magnitude +7.5 , diam. 1.7", phase $79 \%$. Finally, Neptune is a morning object in Aries, magnitude +7.9, diam. 2.3", phase 68\%.
